### Lecture 65. Multidimensional Arrays

The compiler does type checking for us. Remember, c++ is statically typed which means that a lot of errors are caught by the compiler.

This is very different from other languages like Python and Ruby and so forth, where they do all this type checking at runtime.

C++ does it at compile time. So when the program is running, your guarantee that this is going to be correct because it's already done a lot of this checking for you.
